ABSTRACT

A method for creating and administering a website hosted on a server includes normalizing the data as it is entered on the server. The data is stored at the server and all of the data is tagged when stored on the server with the respective tag to convert the data to objects, having desired associated properties as defined by the tags. The tags are then linked to desired locations within the website. Information regarding potential authorized users is stored at the server. Upon accessing of the website, the server determines the aggregate user's rights and enables editing and administrative privileges to the user based upon those rights. The website also changes its appearance to indicate to the user which access rights are currently enabled.
